Name:	Lucius	610	

Lab Section time: 5000

Exam 1 CMSC 152 11:30am Winter 2020

Short Answer:	/30
Tracing Code:	/20
Iterative coding:	/25
Recursive coding:	/25
Total:	/100

You are allowed one hand-written double-sided page of notes, and one reference sheet. No electronic devices may be used at any time. No one may leave the exam room and return to continue working on the exam. No hats may be worn that obscure students' eyes

1. Short Answer (30 pts)

a. What is the result and type of the following expressions in C (2 pt each):

Expression	Value	Туре	
(char)('a'+4)	(2,	cher	
34/20	(1)	104	
14 % 4	2	int	
strlen("I can do this!!");	16	int	

b. Answer the following questions about this line of code:

float da[] = $\{4.5, 7.3, -1.0, 10.3, 6.4, 7.9\};$

(3 pts) This allocation creates an <u>ccred</u> consisting of 6 elements, each of type $\frac{\text{Flock}}{\text{Consisting of }}$

(2 pts) What is the value of da[4]? <u>\langle .u</u>

(2 pts) What is the value of *(da + 3)? $\frac{10.3}{}$

(2 pts) Draw a picture of what the memory looks like after the declaration & initialization line.

1 (3 pts) Explain the difference in how the asterisk is used for: int *a; and *a = 5;

c. (2 pts) How do you decide which functions to add to the .h file?

```
You all the prototypes of the functions written in the . a file that you want to
be able to use in the main. a file
```

d. (2 pts) Write the line of code in blah_main.c that makes it read in the contents of blah.h

```
#include "blah.h"
```

? e. (6 pts) Consider the functions foo and bar. bar calls foo.

```
void foo(int *ar, int *len, int v, int *w) & (4, 6,3,1)
void bar()
                                                {
{
                                                        *w = ar[(*len) - 2]; \omega = 4
        int error, va = 3, wi = 1;
                                                        v = 2;
        int arr[] = \{4, 7, 89, 5, -1, 0\};
                                                        ar[v]++; 5
        int length = 6;
                            6
        error = foo(arr, length, &val, &wi);
                                                        *len = 5;
```

Identify the parameters as in parameter, out parameter, in/out both, or not a pointer. I give you v as an example.

v W len ar not a pointer aut in/out both in

2. Tracing Code (20 pts)

a. (10) Draw, in the right column, the output for the call print_shape(7)

```
void print row(unsigned int n)
                                                          Output
     int i;
     for(i=0;i<n;i++)
                                        *** * * * * /~
          printf("*");
                                        *** * */2
     printf("\n");
                                        44 + In
}
                                        * /w
void print shape(int n)
     if (n <= 0)
          return;
     print row(n);
     print shape (n-2);
}
```

b. (10) Draw, in the right column, the output of this program.

```
void print(unsigned int n)
                                                      Output
    printf("%u\n",n); }
                                                 17510
int main()
                                                 120/2
                                                 20 In
     unsigned int m = 20, n = 140;
                                                 14015
     unsigned int *pB = &n, *pA = &m;
                                                *== *1~
     if (n > 100)
          print(n+38); No
                                                 20 In
     else if (m < 50)
                                                  15 14
          print(n+10);
                                                  15 In
     else
                                                  15 In
         print(n+5);
     if (m < 40)
         print(n+100);
     if (n < 170)
          print(n);
     else
         print(n+17);
     print(*pA);
     print(*pB);
                           かり 一つ
     *pB = 20;
     if (pA == pB)
         printf("==\n");
     if (*pA == *pB)
          printf("*==*\n");
     pA = pB;
                          *PA
     *pA = 15;
                           print(m);
     print(n);
                          * PB
     print(*pA);
     print(*pB);
}
```

```
3. Iterative Coding (25 pts)
/* min_max - a function that calculates the number of lowercase and uppercase letters in a string.
* the results are placed in lower and upper. You may not call any functions within this code.
* If the string has length 0, then return 0. Otherwise, return 1.
* in parameters:
* char *str - a pointer to the first character of the string
* out parameters:
* int *lower – used to store the number of lowercase letters
                                          HENOMIN OF COOL OF O.
* int *upper - used to store the number of uppercase letters
* return value:
* uint - 1 if success, 0 if the string length is 0
typedef unsigned int uint;
uint lower_upper(char *str, uint *lower, uint *upper)
   vint is
     if (* str == 110')
     return 0;
    For (1=0; *(str +i) != (10); ++)
         //lower croe croe
if (*(str+i) >= 'a' && *(str+i) <= 'z')
          # UPPER ++;
```

return li
